Shipboard acoustic doppler current profiler for deep water

Overview

Acoustic Doppler Current Profiler (ADCP) transmits acoustic pulses from a transducer assembly. The transducers receive backscattered sounds from small particles floating with water currents. Using the Doppler shift principle, the backscattered sound data can be converted into components of water current velocity at multiple depths. The shipboard ADCP mounted on R/V KAIMEI can measure the speed and direction of water currents for up to 128 layers. R/V KAIMEI is equipped with two shipboard ADCP, for shallow water (ADCP-S) and for deep water (ADCP-D), and both of them are operated simultaneously. The dataset provided here is a 5-minute time average of absolute velocity data (i.e., water current velocity in geophysical coordinates) after various kinds of corrections only for ADCP-D data. This data processing was carried out by DMO. See [here](#) for detailed correction methods.

* Standard deviations of the ship's speed and the ship's heading, roll, and pitch in each 5-minute average section are also included in the dataset, since data quality of ADCP velocity might be dropped due to the high variabilities of each variables. However, DMO doesn't make any evaluation for the ADCP data by them.
